

# Max External Tutorial

Version 2.2 (March, 1999) by Ichiro Fujinaga

This document is a tutorial for writing external objects for Max 3.5.x. It assumes that the reader is familiar with the Max environment and the C Programming Language. This document is intended to expand upon the material presented by David Zicarelli in his *Writing External Objects for Max* (1996) and is based on a tutorial started by Dale Stamman while at McGill University. It is strongly recommended that the reader study both documents before attempting to create an external Max object. Several examples are provided to demonstrate this process. Max externals (external objects) can be created using Think C, Symantec C++, and CodeWarrior.

This version (2.0) describes the development of Max externals (PowerPC only) using CodeWarrior on PowerPC. If you are using Think C or Symantec C++ compilers or on 68k machines please refer to the version 1 of this document.

## Developing Max External Object with CodeWarrior

---

This tutorial will explain how to create PowerPC native Max externals using MetroWerks Codewarrior (Pro 2 or later) Refer also to Zicareli (1996, 12–8). A very simple external object called **bang** will be created. Refer to Figure 1. for the source code of **bang.c**. The explanation of how **bang** works and writing Max external objects is provided later. First, some preparations are in order.

### Creating a PPC Max External Object (shared library) with CodeWarrior Pro

---

1. Make sure both Max 3.5.x with Software Developers Kit and CodeWarrior are properly installed.
2. Launch CodeWarrior IDE.
3. Select **New Project...** from the **File** menu.
4. In the dialog box (**Select project stationary**), use the **MacOS:C\_C++:Standard Console:Std C Console PPC**. Name the new project, e.g., **bang.µ** (**option-M**). A Project window named **bang.µ** should open.
5. Remove the **ANSI Libraries** folder in the project window by clicking on the name then select **Remove Selected Items** in the **Project** menu.
6. Remove the **Sources** folder in the project window by clicking on the name then select **Remove Selected Items** in the **Project** menu.
7. Select **New** from the **File** menu. Enter the C source code into this window or copy a source file (**bang.c**) into the folder then drag-and-drop the file into the **Project** window.
8. Select **Add Files...** from the **Project** menu to add **MaxLib**, which can be found in **Max::Software Development Kit::Max #includes**, to the project. (Close the **Access Path** message box.) If you are writing **MSP** externals, you will also need to add **SoundLib** and **Max Audio Library**.
9. Select **PPC Std C Console Settings...** from the **Edit** menu. Select **PPC Target** from the **Target Settings Panels**. Change the **Project Type** from **Application** to **Shared Library**, Change the **File Name** to name of the object, e.g., **bang**, **Creator** to **max2**, and **File Type** to **????**.

10. Select PPC Linker from the Target Settings Panels. Uncheck Generate SYM File. Type main in Main: under EntryPoints.
11. Select PPC PEF from the Target Settings Panels. Check Expand Uninitialized Data. Close the PPC Std C Console Settings window and save it.
12. To compile the code, select Make from the Project menu.
13. Run Max on a PPC Mac. Create a new patcher and create a new box. Type the object name into the box and external object will be created. The location of the object should be specified in the File Preferences... in the Options menu of Max.

[see also Zicarelli (1996, 12-4)]

```

// bang.c -- A very simple Max external object.
//           Outputs a bang when a bang is received.
//           97/03/08 IF
//           98/01/13 IF CodeWarrior/PPC only version

#include "ext.h" // Required for all Max external objects

void *this_class; // Required. Global pointing to this class

typedef struct bang // Data structure for this object
{
    Object b_ob; // Must always be the first field; used by Max
    void *b_out; // Pointer to outlet. need one for each outlet
} Bang;

// Prototypes for methods: need a method for each incoming message
void *bang_new(void); // object creation method
void bang_bang(Bang *bang); // method for bang message

void main(void)
{
    // set up our class: create a class definition
    setup(&this_class, (method) bang_new, 0L, (short)sizeof(Bang), 0L, 0);

    addbang((method) bang_bang); // bind method "bang_bang" to the "bang" message
}

void *bang_new(void)
{
    Bang *bang;

    // create the new instance and return a pointer to it
    bang = (Bang *)newobject(this_class);

    bang->b_out = bangout(bang); // create a bang outlet

    return(bang); // must return a pointer to the new instance
}

void bang_bang(Bang *bang)
{
    outlet_bang(bang->b_out); // simply bang!
}

```

**Figure 1. Source code for bang.c**

## Writing Max External Objects

---

To create an external Max object, you write a code resource (68k) or a shared library (PPC). When you type the name of your object into an empty box in a Max patcher window, its code resource file is opened and its contents loaded into memory. The object is then created and able to receive messages from the Max environment. How your object will respond to the various messages is determined by the code you have written.

Your code for an external Max object will consist of a main function and functions (methods) that respond to specific Max messages sent to your object by the Max environment.

The structure of a minimal external object can be divided into four sections:

- initialization\
- main()
- definition of the method to create a new object
- definition of methods that bind to other messages

The initialization consists of the necessary #include files, object structure definition, global variable declarations, and function prototypes. The main function, which is called only once when the user types the name of your object into a box in a Max patcher window for the first time, will define your object's class via `setup()` function and binds methods that will be used for incoming messages. The only requisite method for any class definition is the method that creates new objects. Within this method, memory for the new object is allocated and inlets and outlets are defined. Finally, methods that respond to other messages and other functions are defined. An explanation of each of these four sections are given below using a very simple object called **bang**, which simply outputs a bang upon a bang input. (See Figure 1 for the complete source code.)

### The **bang** object: Initialization

---

The following lines are required for all objects:

```
#include "ext.h"           // Required for all Max external objects
void *this_class;        // Required. Global pointing to this class
```

The next step is to define a data structure for the **bang** Max object. This structure *must* start with a field called an Object. The Object contains references to the **bang** object's class definition as well as some other information. It is used by Max to communicate with the **bang** object. The following is the data structure for the **bang** object:

```
typedef struct bang      // Data structure for this object
{
    Object b_ob;         // Must always be the first field; used by Max
    void *b_out;        // Pointer to an outlet
} Bang;
```

It is a Max convention to start the names of each field in the data structure with a lower case letter followed by an underscore (e.g. `b_out`).

After the object's data structure has been declared, the class methods that will respond to Max messages need to be declared. Your object will do its work by responding to messages from the Max environment. Objects commonly receive integer and float messages in their inlets. Your object's methods will process these numbers in some way and then send out messages using the object's outlets.

Your code must include methods (functions) that can respond to each message your Max object will receive. The **bang** object will receive a “new” message when someone types its name into a box in a Max patcher window. Therefore it is necessary to provide a method that will handle this message and create a new instance of the **bang** object. The **bang** object is also expected to sent out a “bang” message on the outlet, upon a receipt of a “bang” in the left inlet. Methods will have to be written to handle this message. The declaration (prototypr) of these methods is shown below.

```
// Prototypes for methods: need a method for each incoming message
void *bang_new(void);      // object creation method
void bang_bang(Bang *d);  // method for bang message
```

## The **bang** object: main()

---

When your object is created by Max for the first time, Max will load your code resource into memory and create the first instance of your class. At this time, Max will call your code resource’s main function once and only once. The main function specifies how your object should be initialized. The main function needs to do the following:

1. Set up your class: allocate memory for the object and specify methods for the creation of instances of your object.
2. Define messages that the object can respond to and bind each message to a method.

Here is the main( ) function of the **bang** object:

```
void main(void)    // main receives a copy of the Max function macros table
{
    // set up our class: create a class definition
    setup((&this_class, (method) bang_new, 0L, (short)sizeof(Bang), 0L, 0);
    addbang((method) bang_bang); // bind method "bang_bang" to the "bang" message
}
```

The setup function creates a definition of the **bang** object class, which will be used by the `bang_new` method to create new instances of the **bang** object. In the above call to the setup function for the **bang** object, `this_class` is the global variable declared at the beginning of the code. The second argument, `bang_new`, is a pointer to the instance creation method `bang_new`. This is the method that will be called when the object receives a “new” message from the Max environment. Since the **bang** object does not require any special memory cleanup when it is removed from the Max environment, `0L` is used in place of a pointer to a `bang_free` method. The memory occupied by the **bang** object and all of its inlets and outlets will be removed automatically by Max.

The next argument to setup allocates memory for the class. In this example, `sizeof(Bang)` is used to determine the number of bytes of memory needed. Since we are not creating a user interface object, the next argument to `menufun` will be `0L`. The final `0` indicates that there is no argument to this object.

As mentioned above, the code must provide a method for each message you want to respond to. In the main function, each method should respond to the message with the functions: `addint`, `addinx`, `addbang`, `address`, or `addft`. Since the **bang** object only responds to the “bang” message, only one method, `bang_bang`, is needed. In order to bind the `bang_bang` method, which will output a “bang”, to a “bang” input message, we use the routine `addbang(bang_bang)`.

## The **bang** object: The object creation function

---

When a user creates a new instance of your object by typing the name `bang` into a box in a Max patcher window, opening a file with your object already in it, or by cutting and pasting your object, your object will receive a “new” message. This is a request to your creation method to create an object that is an instance of your class. The creation function then handles any arguments that were typed in the box in the Max patcher window, initializes data fields, and creates the object’s inlets and outlets. Finally, the creation function returns a pointer to the new instance of the object. These actions are shown in the method `bang_new` listed below.

```
void *bang_new(void)
{
    Bang *bang;

    // create the new instance and return a pointer to it
    bang = (Bang *)newobject(this_class);

    bang->b_out = bangout(bang); // create a bang outlet

    return(bang);           // must return a pointer to the new instance
}
```

The function, `newobject`, is used to create a new instance of the class **bang**. The argument, `this_class`, is the global variable that points to this class. This pointer was set by the setup function in the main function.

When your object is created, Max automatically creates one inlet, but other inlets and outlets must be explicitly defined. Using the `bangout` function, an outlet (that only outputs “bang” messages) will be created and returns a pointer, which will be stored in the object’s data field `b_out`.

Finally, `bang`, the pointer to the new instance of our object that was returned by the call to `newobject`, must be returned from the function `bang_new`.

Now we have a new instance of our object represented as a “bang” box in a Max patcher window. It is now waiting to receive “bang” messages that will cause its method to do the specified operation, namely, output a “bang”. We will now examine how this is done.

## The **bang** object: Handling the “bang” message

---

```
void bang_bang(Bang *bang)
{
    outlet_bang(bang->b_out); // simply bang!
}
```

When a “bang” message arrives at the object’s left inlet, the `bang_bang` function (method) is called. This happens, because in the `main()` the “bang” message was bound to this function `bang_bang()` by the function:

```
addbang(METHOD bang_bang);
```

The `bang_bang` method simply sends a “bang” messages via the outlet. The method calls the Max function `outlet_bang` to cause the “bang” to be output. In the object creation function, `bang_new` (see above), an outlet was created for this object with the statement:

```
bang->b_out = bangout(bang);
```

This function returned a pointer to the object’s outlet which we stored in the struct field `bang->b_out`.

## The **add** object: Inlets and arguments

---

A simple object **add** will be used to introduce how to add inlets and arguments to your object. This object basically functions as the Max built-in “+” object. It outputs the sum of two integers: the number coming in on the left inlet plus the number stored in the object which can be either specified via the right inlet or in the argument inside the object’s box. The source code is shown in Figure 2.

```

/*  add.c -- 97/03/24 IF (based on Dale Stammen's diff)
**          98/01/14 for PowerPC only
**  This code resource defines an object similar to the standard "+" max object.
**  The add object has 2 inlets and 1 outlet. Left inlet accepts bang and integers,
**  right inlet accepts integers, and outlet outputs the adderence of the 2 inputs.
*/

#include "ext.h"          // Required for all Max external objects

typedef struct add // Data structure for this object
{
    Object a_ob;         // Must always be the first field; used by Max
    long a_valleft;     // Last value from left outlet
    long a_valright;    // Last value from right outlet
    long a_valtotal;    // Value to be sent to outlet
    void *a_out;        // Pointer to outlet, need one for each outlet
} Add;

// Prototypes for methods: you need a method for each message you want to respond to
void *add_new(long value); // Object creation method
void *add_int(Add *add, long value); // Method for message "int" in left inlet
void *add_inl(Add *add, long value); // Method for message "int" in right inlet
void *add_bang(Add *add); // Method for bang message
void *add_assist(Add *add, Object *b, long msg, long arg, char *s); // Assistance method

void main(void) // main receives a copy of the Max function macros table
{
    // set up our class: create a class definition
    setup(&this_class, (method)add_new, 0L, (short) sizeof(Add), 0L, A_DEFLONG, 0);

    addbang((method)add_bang); // bind method "add_bang" to the "bang" message

    addint((method)add_int); // bind method "add_int" to int's received in the left
inlet

    addinx((method)add_inl,1); // bind method "add_inl" to int's received in the right
inlet
}

/*****
add_new(long value)

inputs:      value -- the integer from the typed argument in the object box
description: creates a new instance of our class add. Called once when the code
resource is loaded.
returns:     pointer to new instance
*****/

void *add_new(long value)
{
    Add *add;

    add = (Add *)newobject(this_class); // Create new instance and return a pointer to
it

    add->a_valright = value; // Initialize the addition value
    add->a_valleft = 0;
    add->a_valtotal = value;

    add->a_out = intout(add); // Create our outlet

```

```

    intin(add,1);          // Create the right inlet
    return(add);         // Must return a pointer to the new instance
}

/*****
add_int(Add *a, long value)

inputs:      add      - pointer to Add object
            value     - value received in the inlet

            value as well as the total and outputs the total.
returns:     nothing
*****/

void *add_int(Add *add, long value)
{
    add->a_valleft = value; // Store the value received in the left inlet

    add->a_valtotal = add->a_valleft + add->a_valright; // Add the right inlet value with
the left

    add_bang(add);        // Call bang method right away since it's the left inlet
}

/*****
add_inl(Add *add, long value)

inputs:      add      - pointer to our object
            value     - value received in the inlet
description: stores the new right value, calculates and stores the new adderence between
            the left and right value
returns:     nothing
*****/

void *add_inl(Add *add, long value)
{
    add->a_valright = value;          // Store the value

    add->a_valtotal = add->a_valleft + value; // Update new total
}

/*****
add_bang(Add *a)

inputs:      add      - pointer to our object
description: method called when bang is received: it outputs the current sum of the left
            and right values
returns:     nothing
*****/

void *add_bang(Add *add)
{
    outlet_int(add->a_out, add->a_valtotal); // simply put out the current total
}

```

**Figure 2. Source code for the add object**

## The **add** object: Initialization

---

The data structure for the add object is shown below. Note that three values are stored within the object.

```
typedef struct add // Data structure for this object
{
    Object a_ob;           // Must always be the first field; used by Max
    long a_valleft;       // Last value sent to left outlet
    long a_valright;      // Last value sent to right outlet
    long a_valtotal;      // Value to be sent to outlet
    void *a_out;          // Pointer to outlet, need one for each outlet
} Add;
```

In the setup function in main() now has A\_DEFLONG argument indicating that the object accept one integer argument in the object box.

```
setup(&this_class, add_new, 0L, (short)sizeof(Add), 0L, A_DEFLONG, 0);
```

Three methods are bound with the three types of messages: “bang” in the left inlet, integer entered in the left inlet, and integer entered in the right inlet.

```
addbang((method)add_bang); // bind "add_bang" to the "bang" message
addint((method)add_int);   // bind "add_int" to int received in the left inlet
addinx((method)add_inl,1); // bind "add_inl" to int received in the right inlet
```

## The **add** object: The object creation function

---

Unlike the **bang** object above, the add\_new function is passed an integer argument from the object box that the user may type. The object’s variables are initialized, an outlet that output integer is created and the right inlet, which accepts integer is also created:

```
void *add_new(long value)
{
    Add *add;

    add = (Add *)newobject(this_class); // Create new instance and return a pointer to it

    add->a_valright = value; // Initialize the add values
    add->a_valleft = 0;
    add->a_valtotal = value;

    add->a_out = intout(add); // Create our outlet

    intin(add,1); // Create the right inlet

    return(add); // Must return a pointer to the new instance
}
```

## The **add** object: Methods

---

The add\_int method is called when an integer comes in on the left inlet. It stores the value in a\_valleft, adds that value with a\_valright, storing the result in a\_valtotal, then calls the add\_bang method to output the result.

```
void *add_int(Add *add, long value)
{
    add->a_valleft = value; // Store the value received in the left inlet
    add->a_valtotal = add->a_valleft + add->a_valright; // Add the right inlet value with
the left
```

```

    add_bang(add);           // Call bang method right away since it's the left inlet
}

```

The `add_in1` method is called when an integer comes in on the right inlet. It stores the new value in `a_valright` then updates the `val_total`.

```

void *add_in1(Add *add, long value)
{
    add->a_valright = value;           // Store the value
    add->a_valtotal = add->a_valleft + value; // Update new total
}

```

The `add_bang` method is called when a “bang” comes in the left inlet or, indirectly via `add_int` method, when an integer comes in the left inlet.

```

void *add_bang(Add *add)
{
    outlet_int(add->a_out, add->a_valtotal); // simply put out the current total
}

```

## The `add_assist` object: Adding to the Max’s New Object list and assistance messages

Two enhancements will be added to the **add** object: the object (**add\_assist**) will be included in the Patcher’s **New Object** list and the assistance messages, which appears when the mouse is pointed at object’s inlets and outlets. The complete listing of **add\_assist** object is in Figure 3.

To make an entry in the New Object list is very simple. All you need to do is to include the following function in your `main()`:

```
finder_addclass("All Objects", "add_assist"); // add class to the New object list
```

If you want to add the object to the "Arithmetic/ Logic" list, you could add the following:

```
finder_addclass("Arithmetic/Logic", "add_assist");
```

In order to add the assistance messages: a method must be defined, which must be bound to the Max message “assist”, and since we will be using a resource for the string for the assistance messages, we need to copy the string from the resource. The binding and the copying is done in the `main()` as follows:

```

address((method)add_assist, "assist", A_CANT, 0); // bind method add_assist to the
// assistance message

rescopy('STR#', ResourceID); // copy the assistance messages resource into Max's temp
file

```

`ResourceID` is a number that you define when creating the string resource. The `rescopy` function copies the string to Max’s temporary file (**Max Temp 1** in the **Temporary Items** folder). How to create this resource is explained next. The explanation of the `add_assist` method will follow.

## Creating a String Resource in ResEdit 2.1 for a Max External Object

---

1. Launch ResEdit.
2. Click on the clown to get rid of it.
3. Select New... from the File menu; move to your project folder.
4. Name your resource file with EXACTLY the same name as your project and append the name with .rsrc. For example, if your project is called projectname.µ, name your resource projectname.µ.rsrc.
5. Click the New button
6. Select Create New Resource from the Resource menu.
7. Scroll down to the resource type STR# in the Select New Type window. Make sure you select STR# and not STR. Click on OK.
8. ResEdit will now create a window called STR# ID = 128. Click on the field 1) \*\*\*\*\*. Select Insert New Field(s) from the Resource menu. In the box after The string, type in your external Max object's assistance string for the first inlet. You may use a maximum of 60 characters. Repeat step 8 for as many inlets and outlets as your Max object will need. Create them in order, with the first string being the message for inlet 1, the second for inlet 2.
9. Select Get Resource Info from the Resource menu. Enter your resource ID number in the field ID:. This number MUST match the resource ID number you define in your Max object. If you wish, you may type in the name of your resource in the field Name. This will help you remember what the resource is used for in the "resource picker window".
10. Save your resource. Make sure it is saved to your project folder and that it has the same name as your project file with .rsrc added to the end of the name.

## The **add\_assist** object: add\_assist method

---

```
void *add_assist(Add *add, Object *b, long msg, long arg, char *s)
{
    EnterCallback();

    // copy the appropriate message to the destination string
    assist_string(ResourceID, msg, arg, 1, 3, s);
    ExitCallback();
}
```

In the argument list for **add\_assist**, *d* is a pointer to our object, *b* is a pointer to the object's box in the Max patcher window. *msg* will be one of two values: 1 if the cursor is over an inlet or 2 if it is over an outlet. *arg* is the inlet or outlet number starting at 0 for the left inlet. *s* is where you will copy a C string containing your assistance information.

The function `assist_string` handles the posting of the assistance string in the assistance area of the Max patcher window. It will copy the correct string from the resource in the memory specified by `ResourceID`. (`ResourceID` was defined at the beginning of the code.) This resource was copied into the Max's temp file by `rescopy()` in the `main` function. *msg* specifies if either an inlet or outlet was selected and *arg* is the inlet or outlets number. The argument 1 specifies that the first string in the resource corresponds to the first inlet. Likewise, the argument 3 specifies that the third string in the resource goes with the first outlet. The function

`assist_string` will copy the selected resource string into `s`, which will then be displayed in the assistance area of the patcher window.

```

/*  add_assist.c -- 97/03/24 IF (based on Dale Stammen's diff)
**                               98/01/14 for PowerPC only IF
**  This code resource defines an object similar to the standard "+" max object.
**  The add object has 2 inlets and 1 outlet. Left inlet accepts bang and integers,
**  right inlet accepts integers, and outlet outputs the adderence of the 2 inputs.
*/

#include "ext.h"          // Required for all Max external objects

void *this_class;       // Required. Global pointing to this class

#define ResourceID 3999 // resource ID# for assistance strings created in ResEdit

typedef struct add // Data structure for this object
{
    Object a_ob;        // Must always be the first field; used by Max
    long a_valleft;    // Last value sent to left outlet
    long a_valright;   // Last value sent to right outlet
    long a_valtotal;   // Value to be sent to outlet
    void *a_out;      // Pointer to outlet, need one for each outlet
} Add;

// Prototypes for methods: you need a method for each message you want to respond to
void *add_new(long value); // Object creation method
void *add_int(Add *add, long value); // Method for message "int" in left inlet
void *add_inl(Add *add, long value); // Method for message "int" in right inlet
void *add_bang(Add *add); // Method for bang message
void *add_assist(Add *add, Object *b, long msg, long arg, char *s); // Assistance method

void main(void) // main receives a copy of the Max function macros table
{
    // set up our class: create a class definition
    setup(&this_class, (method)add_new, 0L, (short) sizeof(Add), 0L, A_DEFLONG, 0);

    addbang((method)add_bang); // bind method "add_bang" to the "bang" message
    addint((method)add_int); // bind method "add_int" to int's received in the
    // left inlet
    addinx((method)add_inl,1); // bind method "add_inl" to int's received in the
    // right inlet

## The **minimum** object: Float, Atom, and list

---

Thus far, the only data type we have been using is an integer type, namely long. In this section, we'll introduce the float data type, the Atom data type, and the list, which is an array of Atoms.

The float data type is similar to long except that it involves floating-point numbers. Max provides macros and functions to handle floats very similar to longs, e.g., to add left inlets you would use:

```
addint(long_method);
```

for inlet that accepts long and use:

```
addfloat(float_method);
```

for inlet that accepts float.

An Atom is a special data type (a structure) that allows any of the four data types (long, float, Symbol, Object) used in Max to be stored. Here is how it is defined:

```
union word          /* union for packing any data type */
{
    long            w_long;
    float           w_float;
    Symbol          *w_sym;
    Object          *w_obj;
};

typedef struct atom  // and an atom which is a typed datum
{
    short           a_type; // from the defs below
    union word      a_w;
} Atom;
```

The struct member `a_type` specifies what type of data is stored in `a_w`, and it could be any of the following:

```
#define A_NOTHING    0    // ends the type list
#define A_LONG       1    // Type-checked integer argument
#define A_FLOAT      2    // Type-checked float argument
#define A_SYM        3    // Type-checked symbol argument
#define A_OBJ        4    // for argtype lists; passes the value of sym
#define A_DEFLONG    5    // long but defaults to zero
#define A_DEFFLOAT   6    // float, same default
#define A_DEFSYM     7    // symbol, defaults to ""
```

A list in Max is simple an array of Atoms. A list will be used if you declare a method to receive its arguments with `A_GIMME`, typically in either the setup function:

```
setup(&class, (method)minimum_new, 0L, (short)sizeof(Minimum), 0L, A_GIMME, A_NOTHING);
```

or a method that responds to the "list" message:

```
address((method)minimum_list, "list", A_GIMME, A_NOTHING);
```

Then your method, `minimum_list` in the example above, will be passed a list. This is done by `argc` (short) and `argv` (Atom \*). `argc` is the number of Atoms and `argv` points to the first Atom in the array. Here is an example:

```
void minimum_list(Minimum *x, Symbol *s, short argc, Atom *argv)
```

The Symbol `*s` contains the message itself (in this case, "list"). The object **minimum** illustrates use of these data types (see Figure 4).

```

}

```

**Figure 4. Source code for the minimum object**

## More Atoms and list

---

Max uses Atoms when passing messages between objects. If your object is going to be able to send a list out of its outlet, it will have to use a list of Atoms. Likewise, if you wish to receive lists, or more than 7 typed data in arguments from your object's box in the Max patcher, you will again have to deal with Atoms. Remember, Atoms are simply a struct that have a field of type union that allows them to contain different types of data.

It is now necessary to examine the structure of a message in Max. Consider the following message box:

```
play 100 200 2.5 stop
```

This message box contains 5 items, the symbol "play", the long integers 100 and 200, the float 2.5, and finally the symbol "stop". If this message is sent to your object, your object will actually receive the message "play", followed by a list of 4 atoms containing 100, 200, 2.5 and "stop". In other words, "play" is the message and the remaining items are its arguments. One way to make your object understand this message is to use `address( )` in its main function.

```
address(max_play, "play", A_LONG, A_LONG, A_FLOAT, A_SYM, 0); // bind method max-
play to the "play" message"
```

or with optional arguments, so that if some of the arguments are not specified by the user, the object will set them to a default values:

```
address(max_play, "play", A_DEFLONG, A_DEFLONG, A_DEFFLOAT, A_DEFSYM, 0);
```

But this approach requires that you always have two longs, a float and a symbol in the right order. You are also limited to a total of seven arguments using this declaration method.

There is another way for your object to receive messages and their arguments. When you declare a method to receive its arguments with `A_GIMME`, the arguments will be passed to your object in an `argc, argv` list. More about this `argc, argv` stuff later.

In order to tell Max to give you all of the arguments in a message, you bind your method to the message in your main function with the Max function `address`. For example, to bind the method `atoms_play` with the above message you would write in your main function:

```
address(atoms_play, "play", A_GIMME, 0); // bind method "atoms_play" to the "play"
message"
```

This call binds the method `atoms_play` to the message "play". Whenever the object receives the message "play", Max will call the method `atoms_play` and pass it the message and a list of arguments.

`A_GIMME` tells Max to pass the message and its arguments without typechecking them. You are now responsible for typechecking them yourself.

You now need to write a method that will be able to receive this message and its arguments. The method `atoms_play` would be declared as:

```
void *atoms_play(Example *a, Symbol *mess, int argc, Atom *argv)
```

In this function declaration, `a` is a pointer to your object, `mess` is pointer to the message that called this method (in this example the, “play” message). The integer `argc` is the number of arguments contained in the atom list and `argv` is a pointer to an array of atoms containing the actual arguments. Up to 65,536 arguments can be received by a method.

If your object receives the message “play 100 200 2.5 stop”, Max will call your `play` function. Your `atoms_play` function will receive a pointer to the symbol “play” in `mess`, the integer 4 in `argc`, and finally a pointer to a list of atoms containing the values 100 200 2.5 “stop”. The code in Figure 5 shows you how to typecheck and access the data in the atom list.

```
#define MAX_ARGS 20

typedef struct example          // data structure for this object
{
    Object a_ob;
    Atom  a_list[MAX_ARGS]; // array of Atoms: list
    int   a_size;           // number of Atoms in the list
} Example;

void *atoms_play(Example *a,int argc, Atom *argv)
{
    int i;

    a->a_size = argc;
    if (a->a_size > MAX_ARGS)
        a->a_size = MAX_ARGS;

    for(i = 0; i < a->a_size; i++)
        switch(argv[i].a_type)        // type check each argument
        {
            case A_LONG:
                SETLONG(a->a_list + i, argv[i].a_w.w_long);
                post("argument %ld is a long: %ld", (long) i,argv[i].a_w.w_long);
                break;
            case A_FLOAT:
                SETFLOAT(a->a_list + i, argv[i].a_w.w_float);
                post("argument %ld is a float: %f", (long) i, argv[i].a_w.w_float);
                break;
            case A_SYM:
                SETSYM(a->a_list + i, argv[i].a_w.w_sym);
                post("argument %ld is a symbol: %s",(long) i,
                    argv[i].a_w.w_sym->s_name);
                break;
        }
}
```

**Figure 5. Typechecking an argc, argv list of atoms**

This example receives a list of arguments from Max whenever the object receives the “play” message. It then checks the type of each Atom in the argv list and stores it into an internal array of Atoms. Finally, it reports to the Max window the type and value of the argument.

When working an Atom, you must be able to correctly access its various fields. In Figure 5, we examine the `a_type` field of an Atom to determine the type of data contained in the union. As mentioned above `a_type` will be either `A_LONG`, `A_FLOAT`, or `A_SYM`. These constants are declared in the Max #include file “ext\_mess.h”.

Notice that we use the struct notation `argv[i].a_type` to access the `a_type` field. It is also possible to use the pointer `argv` to access the field, i.e., `(argv + i)->a_type`. You may choose whatever style suits you best.

In the above example, if the Atom contains a long (i.e., `a_type == A_LONG`), we want to store the argument into our internal Atom list, `a_list` as a long. Likewise, if

(a\_type == A\_FLOAT) we would store it as a float, and if (a\_type == A\_SYM) we would store the argument as a symbol. Max provides several macros for storing an item into an atom. These are:

```
SETLONG(Atom *a, long number);
SETFLOAT(Atom *a, float number);
SETSYM(Atom *a, Symbol *s);
```

Here are the current macro definitions as they appear in Max #include file "ext\_mess.h".

```
#define SETSYM(ap, x)      ((ap)->a_type = A_SYM, (ap)->a_w.w_sym = (x))
#define SETLONG(ap, x)   ((ap)->a_type = A_LONG, (ap)->a_w.w_long = (x))
#define SETFLOAT(ap, x) ((ap)->a_type = A_FLOAT, (ap)->a_w.w_float = (x))
```

These macros accomplish two things. First the macro sets the a\_type field of the Atom to the correct type. This means that SETLONG will set the a\_type field of the Atom to A\_LONG, SETFLOAT sets it to A\_FLOAT, and SETSYM sets it to A\_SYM. The macro then puts the long, float, or the pointer to the symbol into the union a\_w. Remember that a pointer to the symbol is stored in the union, and not the actual symbol.

In the above example we used the following line of code to call SETLONG:

```
SETLONG(a->a_list + i, argv[i].a_w.w_long);
```

In this call, a is a pointer to our Object. We use it to access the array of Atoms called a\_list that is in our object's data structure. Since SETLONG requires a pointer to an Atom, we must give it a pointer to the i th Atom in the array. When i == 0, a->a\_list + i is a pointer to the first Atom in the array a\_list. Likewise, if i == 5, a->a\_list + i is a pointer to the 6th Atom in the array.

Notice how we access the long field of the union a\_w in the argv Atom list. We write argv[i] to access the i th Atom in the argv list. argv[i].a\_w accesses the union a\_w field of the struct atom. Finally, argv[i].a\_w.w\_long accesses the long value stored in the union a\_w. We first access the atom, then the union, and finally the data.

Another way of putting a long value into an Atom is:

```
a->a_list[i].a_type = A_LONG;
a->a_list[i].a_w.w_long = 100;
```

Using this method you are responsible for setting the a\_type field yourself.

You can use SETFLOAT the same way as SETLONG. SETFLOAT will set the a\_type field to A\_FLOAT, and place the float value in the float field of the union a\_w (i.e., a\_w.w\_float). To access a float field of an Atom in the argv list in the above example, we write:

```
argv[i].a_w.w_float OR (argv + i)->a_w.w_float
```

Likewise, to access this value in our internal array of Atoms we write:

```
a->a_list[i].a_w.w_float OR (a->a_list + i)->a_w.w_float
```

When you want to store a symbol into an Atom, or access a symbol already in an Atom, you must remember that a pointer to the symbol is stored in the Symbol field of the union a\_w. The field in the union a\_w is defined as Symbol \*w\_sym. Therefore, in order to store a symbol into an Atom you store the pointer to the symbol and not the symbol itself. Likewise, when you access a symbol, you need to access what the pointer in the Symbol field points to. In other words, to get at a symbol, there is yet another stage of indirection.

In the above example, we use SETSYM to set the pointer to the symbol contained in the argv list into our internal Atom list a\_list. Therefore, SETSYM wants a pointer to the symbol as its second argument.

```
SETSYM(a->a_list + i, argv[i].a_w.w_sym);
```

Notice how we post the actual symbol to the Max window. We use the following post function:

```
post("argument %ld is a symbol: %s", (long) i, argv[i].a_w.w_sym->s_name);
```

Note that in order to access our actual symbol, we must access what the symbol pointer points to:

```
argv[i].a_w.w_sym->s_name
```

In the Max #include file "ext\_mess.h" a symbol is defined as the following struct:

```
struct symbol
{
    char *s_name; /* name */
    struct object *s_thing; /* possible binding to an object */
} Symbol;
```

Therefore, in order to access a symbol in an Atom, first access the Atom, then the union a\_w, then the w\_sym field and finally the s\_name field of the Symbol, i.e., argv[i].a\_w.w\_sym->s\_name.

Now that you have a list of Atoms in your object you can send it to an outlet. To do this you need to create a list outlet using the Max function:

```
Outlet *listout (void *owner)
```

In our example we would create the list outlet in the object's creation function example\_new.

```
a->a_list_outlet = listout(Example *x);
```

To send the internal list a\_list out this outlet, one would use the Max function:

```
void *outlet_list(Outlet *x, Symbol *msg, int argc, Atom *argv);
```

We would call this function with the following arguments:

```
outlet_list(a->a_list_outlet, "list", a->a_size, &(a->a_list));
```

where a->a\_list\_outlet is a pointer to the outlet we created with listout, "list" is the message to be sent, a->a\_size is the number of Atoms in the internal Atom list, and &(a->a\_list) is a pointer to the first Atom in this list.

## The **atoms** object:

---

Notice the address functions:

```
address(atoms_list,"play",A_GIMME,0); // bind method "atoms_list" to "play" message
address(atoms_list,"list",A_GIMME,0); // bind method "atoms_list" to "list" message
```

Both of these lines of code cause the function `atoms_list` to be called when the object receives either the “play” message of the “list” message. Also notice that we requested that Max send to our object the arguments of the message as a list of atoms. This was accomplished by using `A_GIMME`.

### The **list** Method

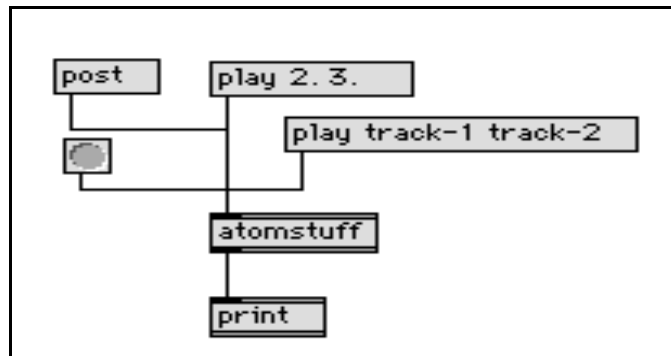

This method receives a list of atoms from Max contain the items of the list sent to your object. The number of items (or atoms) in the list is in `argc`. The actual atoms are stored in `argv`. Actually these are pointers to atoms. We then check each atom for its type before we put it in our list. The list method then sends the list of atoms out its outlet using `outlet_list`. Notice we use `&(a->a_list)` to point to our list of Atoms.

### The **bang** Method

When our object receives the bang message, it simply sends the current contents of its list out its outlet using the `outlet_list` function.

### The **post** Method (Zicarelli 1996, 71)

When the object receives the “bang” message, it posts the contents of its Atom list to the Max window using the function `postatom` (Zicarelli 1996, 72). Here is how to post a list of atoms:

## The **mymetro** object: Clock routines

---

This example uses the **Clock** object (Zicarelli 1996, 60–3), which allows scheduling in Max. The routines associated with the **Clock** objects allows events to happen in the future. This is accomplished by assigning a function to be executed when the clock goes off and indicate when the clock is to go off. More specifically:

1. Use `clock_new()` to create a **Clock** object and assign the function to be executed when it goes off.
2. Use `clock_set()` or `clock_delay()` to schedule the execution of the clock function at absolute time or relative time, respectively. Zicarelli recommends using `clock_delay` rather than `clock_set` (Zicarelli 1996, 61).
3. When the **Clock** is no longer needed, it should be removed with `freeobject` function.

```

/* This code resource defines the object "mymetro" which is similar to the standard
"metro" Max object. The metro object has 2 inlets and 2 outlets.

"bang"   in left inlet starts metronome
"stop"   in left inlet stops metronome
integer  in right inlet sets tempo in ms

left output sends bangs at each metronome interval
right outlet outputs current time

The object also posts messages to the Max window indicating the current state of
mymetro.
